

CSE341 HW1 Report

C-to-Lisp Converter

R.Hilal SAYGIN

Introduction

Developed for C to Lisp code converting task. It focuses on preserving the structure of C programs while converting them into valid Lisp code.

The converter handles key conversion steps

- if statements
- logical and arithmetical operation conversions from c to lisp
- for loops
- variable assignments
- variable definitions in nested structures
- function declarations
- function definitions
- function calls
- printf
- variable assignment by function return.

The code relies on `cl-ppcre` built-in Common Lisp functions for basic operations, lists manipulation, cond structures, regular expression-based string manipulation etc.

1. Line Type Detection and Handling

- **determine-line-type**: Analyses a line of C code and determines its type by using regex matching system (e.g., function definition, if-statement, variable assignment). Regular expressions and string operations are carefully used to distinguish between line types and categorise each line.
- **convert-line**: Based on the line type identified by `determine-line-type`, this function calls the appropriate conversion function. It also manages block tracking, indentation, and ensures that blocks like `if` statements, loops, and functions are correctly opened and closed. Conversion-foo functionality integrated in this function as well.

2. Custom String Manipulation

- Several helper functions like `string-contains`, `string-starts-with`, `string-trim-whitespace`, and `split-params` are implemented to handle common string operations used throughout the project.

3. C to Lisp Conversions for Specific Code Constructs

- **convert-if-statement**: Converts C-style `if` statements to Lisp's prefix-style conditional expressions. It handles the translation of comparison operators (e.g., `!=` to `/=`).

- **convert-condition:** C conditional expressions (e.g., `==`, `!=`, `&&`, `||`, `!`) into Lisp equivalents (`=`, `/=`, `and`, `or`, `not`) and rearranges them into Lisp's prefix notation.
- **convert-printf:** Converts C's `printf` statements to Lisp's format function, handling format specifiers and arguments.
- **convert-for-loop:** Transforms C `for` loops into Lisp `loop` constructs. The conversion handles initialization, condition checking, and incrementing by converting these into equivalent Lisp loop keywords.
- **convert-func-definition:** Converts C function definitions to Lisp's `defun` format. It extracts the function name, parameters, and handles block-level structures within the function.
- **convert-func-call:** Converts C function calls to their Lisp equivalents, with proper handling of arguments and formatting.
- **convert-func-prototype:** Converts C function prototypes into Lisp's `declare` statements, which define function signatures.
- **convert-var-definition:** Converts C variable definitions into Lisp's `let` or `setf` bindings for handling variable declarations and initializations.
- **convert-arithmetic:** Translates C-style arithmetic expressions into equivalent Lisp expressions. It handles the conversion of infix arithmetic to Lisp's prefix notation.
- **Convert-func-return:** Converts C return statements into Lisp return expressions, handling any involved arithmetic or function calls.

4. File Handling

- **read-file:** Reads the contents of a C file line by line and returns them as a list of strings.
- **write-file:** Writes the converted Lisp code for each line to the given output file name.
- **convert-c-to-lisp:** The main entry point of the program. It reads the input C file, processes each line using `convert-c-to-lisp-recursive`, and writes the converted Lisp code to the output file.

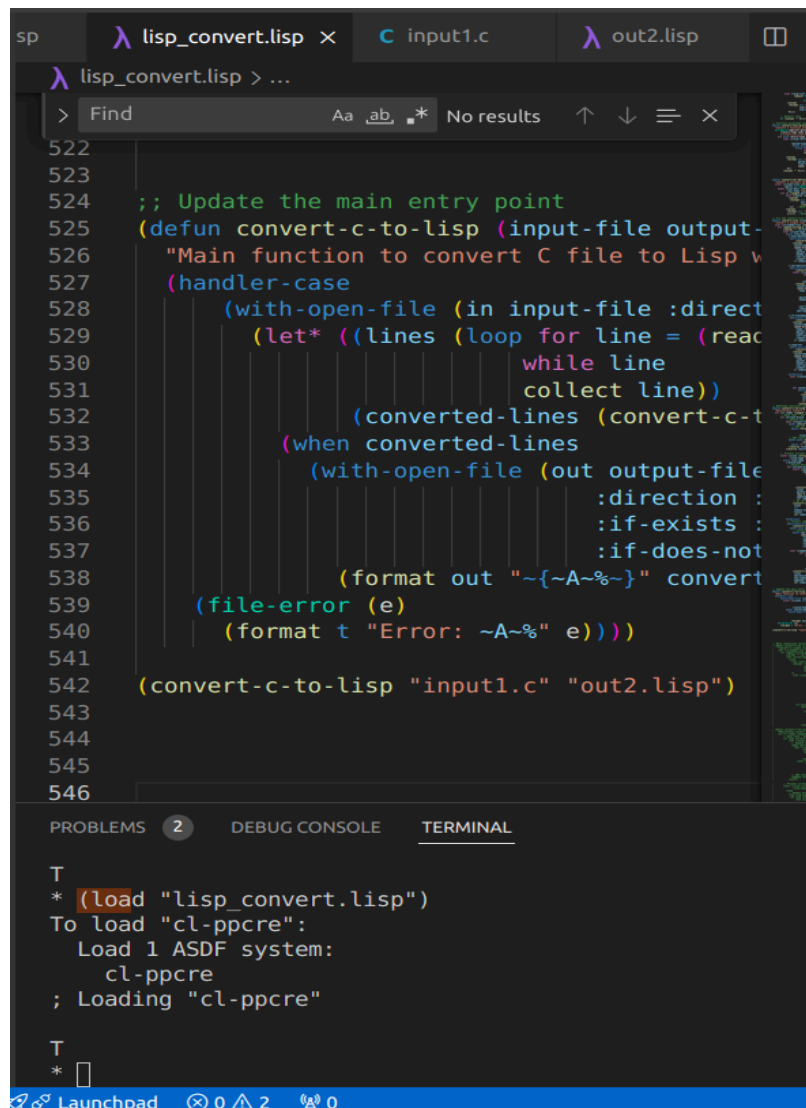

5. Recursive Code Conversion

- **convert-c-to-lisp-recursive:** The main recursive conversion logic. It implements the recursive logic carefully to process each line of C code and convert it to Lisp. It keeps track of blocks (e.g., `if`, `for`, `function`) and their associated indentation levels. As blocks are opened and closed, the indentation and structure of the code are adjusted accordingly.

6. Block Information Management

- **block-info:** A custom structure that holds metadata about blocks of code (e.g., functions, loops). It tracks whether a block needs to be closed, the variables declared in the block, and the current indentation level.

Results

The screenshot shows a code editor with three tabs: `lisp_convert.lisp`, `input1.c`, and `out2.lisp`. The `lisp_convert.lisp` tab is active, displaying a Lisp function `convert-c-to-lisp` that reads a C file and converts it to Lisp. The function uses `with-open-file`, `let*`, `loop`, `while`, `collect`, `when`, and `format`. A search bar at the top of the editor shows "Find" with no results. Below the code editor, the "TERMINAL" tab is active, showing the output of running the Lisp file. The terminal output includes a prompt `T`, a command `* (load "lisp_convert.lisp")`, and a message "To load 'cl-ppcre': Load 1 ASDF system: cl-ppcre ; Loading 'cl-ppcre'". The terminal also shows a prompt `T` and a command `* []`. The bottom status bar of the editor shows "Launchpad" and some icons.
